

Orthogonal linear group-subgroup pairs with the same invariants

S.Solomon*

February 1, 2008

Abstract

The main theorem of Galois theory states that there are no finite group-subgroup pairs with the same invariants. On the other hand, if we consider complex linear reductive groups instead of finite groups, the analogous statement is no longer true: There exist counterexample group-subgroup pairs with the same invariants. However, it's possible to classify all these counterexamples for certain types of groups. In [16], we provided the classification for connected complex irreducible groups, and, in this paper, for connected complex orthogonal groups, i.e., groups that preserve some non-degenerate quadratic form.

1 Introduction

1.1 Setting the problem

Let G be an algebraic group acting on an irreducible algebraic variety X . Consider the action of G on the field of the rational functions $k(X)$. Let $k(X)^G$ denote the subfield of rational G -invariants. Then G is a group of automorphisms of the field extension $k(X)$ over $k(X)^G$, that is, $G \subseteq \text{Aut}(k(X), k(X)^G)$.

Suppose G is a finite group. Then $k(X)/k(X)^G$ is a Galois extension. The main theorem of the Galois theory states that $G = \text{Aut}(k(X), k(X)^G)$. Equivalently, any proper subgroup $H \subsetneq G$ corresponds to a nontrivial extension $k(X)^H \supsetneq k(X)^G$. Simply saying, H always has more invariants than G .

In other words, a finite group action is uniquely determined by its invariants. A natural question arises if this is true for other classes of groups. The

*Hebrew University of Jerusalem, Israel. E-mail: gsasha@math.huji.ac.il

answer in general is "no". The simplest counterexample is $Sp(V) \subset SL(V)$, where V is an even dimensional vector space. For both the group and the subgroup, the only invariants are constants.

However, it is possible to describe all the counterexamples for certain types of group actions.

Definition 1 *We call a triple (H, G, X) exceptional, if the fields of rational invariants of H and G coincide: $k(X)^H = k(X)^G$. If $H = G$ we say that the triple (H, G, X) is trivial.*

A general problem is to classify exceptional triples. We just saw that any exceptional triple (H, G, X) with G finite is trivial. In [16], we classified exceptional triples (H, G, V) , where V is a complex (finite dimensional) vector space, H, G are connected irreducible linear groups, see section 7 here for a partial summary. In this paper, we allow the groups to be reducible but require that they preserve a non-degenerate quadratic form.

1.2 Background

To the best of our knowledge, this problem has not been considered before even for reductive linear groups. However, there are two important classical results in this direction.

E.B.Vinberg in 1959 started, Sato and Kimura [14] in 1977, and Shpiz[15] in 1978, completed the classification of irreducible complex linear groups $G \subset GL(V)$ acting with an orbit open in V , so-called locally transitive groups (alternatively, V is called a prehomogeneous vector space). Such groups cannot have non-trivial polynomial or rational invariants. Thus, any locally transitive group G with a locally transitive subgroup H make an exceptional triple (H, G, V) .

D.Montgomery and H.Samelson[8] in 1943, and A.Borel[1] in 1950, described real groups that act transitively on spheres. Any triple (H, G, S) of a group G and a subgroup H transitive on a sphere S is exceptional.

1.3 Geometric meaning

By Rosenlicht's theorem, a triple (H, G, X) is exceptional if and only if H is locally transitive on a G -orbit in general position $O_X(G)$, that is, the closures of orbits in general position of H and G coincide: $\overline{O_X(H)} = \overline{O_X(G)}$. Note that for stable actions, i.e., where the orbits in general position are closed, it means $O_X(H) = O_X(G)$. In particular, this holds for orthogonal groups H and G .

As a consequence, we obtain

Lemma 1 *Suppose X is irreducible quasiaffine, and the polynomial G - and H -invariants separate (respective) orbits in general position. Then (H, G, X) is an exceptional triple if and only if the polynomial invariants of H and G coincide: $k[X]^G = k[X]^H$. In particular, this holds in case H, G are semisimple, or in case $X = V$ is a vector space, and H, G are orthogonal.*

Proof. "If" is trivial. Suppose (H, G, X) is exceptional. By [17] Proposition 3.4, we have $\text{tr.deg } k[X]^G = \text{codim } O_X(G) = \text{codim } O_X(H) = \text{tr.deg } k[X]^H$, hence $k[X]^G = k[X]^H$. "In particular" statement follows from [17] Theorem 3.3 $\square$

1.4 Main results

Let $X = V$ be a vector space over $\mathbb{C}$. The main result is the following Theorem 1 that classifies exceptional triples (H, G, V) under the assumption that H, G are connected semisimple orthogonal groups. Furthermore, Proposition 1 gives a criterion for an exceptional triple (H, G, V) , where H, G are connected reductive orthogonal and at least one of them is not semisimple.

Assume $H \subset G \subset GL(V)$ are semisimple linear groups.

We assign a three level diagram to the triple (H, G, V) . The upper and the middle level vertices correspond to normal subgroups of H and G , respectively. If a normal subgroup of H projects nontrivially on a normal subgroup of G , we connect the vertices with an edge, and sometimes specify the projection on the side of the edge. A double edge means that the projection is an isomorphism. We substitute one of the ends of a double edge with a circle. The lower level vertices correspond to a decomposition of V into G -submodules. We connect each submodule vertex with all normal subgroups of G that act nontrivially on this submodule. Unspecified subgroups and submodules, that is, circles, can be considered arbitrary.

A diagram that has two connected components corresponding to triples (H_1, G_1, V_1) and (H_2, G_2, V_2) encodes the direct sum of these triples, i.e., the triple $(H_1 \times H_2, G_1 \times G_2, V_1 \oplus V_2)$. The direct sum of exceptional triples is exceptional, and, vice versa, if the direct sum is exceptional, then every summand is exceptional. A triple (or a linear group) that cannot be decomposed into a nontrivial direct sum is called *indecomposable*.

We say a triple (H, G, V) is *locally trivial* if the restriction (H, G, U) to every proper G -submodule $U \subsetneq V$ is a trivial triple. Also, we call G *strongly faithful* if all nonzero G -submodules of V are faithful. We say a

triple (H, G, V) is strongly faithful if G is such.

Finally, we may always assume for our purposes that H is maximal in G . Indeed, if (H, F, X) and (F, G, X) are exceptional triples then (H, G, X) is also exceptional. Conversely, if (H, G, X) is exceptional, then (F, G, X) is exceptional for any $F \supset H$.

Theorem 1 *Let (H, G, V) be an indecomposable nontrivial exceptional triple, where H, G are connected semisimple orthogonal, and H is maximal in G . Then (H, G, V) is either locally trivial with diagram one of **T1** – **T9**, or strongly faithful with diagram one of **F1** – **F10**, or (H, G, V) has a diagram **O**, where*

(i) *in diagram **T9** one of the two indecomposable components of group G satisfies the explicit criterion of Lemma 18; and*

(ii) *in diagram **O** the action of the subgroup $SO_8 \subset G$ on $V_1 \oplus V_2$ is isomorphic, up to a trivial component, to $t\phi_1$, $t \leq 3$, where ϕ_1 stands for the tautological action of SO_8 on $\mathbb{C}^8$.*

Conversely, all the abovementioned diagrams correspond to exceptional triples.

In the diagrams below, ν stands for $\nu(H, G, V) := \text{tr.deg.}\mathbb{C}(V)^H = \text{tr.deg.}\mathbb{C}(V)^G$, $\nu = 4 + \text{tr.deg.}\mathbb{C}(U)^{\tilde{G}}$ in diagram **T8**. See section 3 for other notation.

T1, $\nu = 2$

T2, $\nu = 2$

T3, $\nu = 2$

Proposition 1 *Let $H \subsetneq G \subset SO(V)$ be connected reductive orthogonal groups. Let $Z(G)$ and G' denote the center and the commutator subgroup of G , and let $T \subset Z(G)$ denote a complement subgroup to the projection of $Z(H)$ on $Z(G)$. Then (H, G, V) is exceptional if and only if*

- (i) *the triple (H', G', V) is exceptional, and*
- (ii) *T acts trivially on $\mathbb{C}[V]^{H'} = \mathbb{C}[V]^{G'}$.*

2 Acknowledgments

No words would suffice to express my gratitude to E.B.Vinberg, my teacher. I am grateful to A.Shalev, my advisor at Hebrew University of Jerusalem, Israel. I would like also to thank Michael Larsen for a helpful discussion, D.I.Panyushev for remarks, and O.Yakimova for pointing out Lemma 18. My family provided me with continuous inspiration.

3 Notation and agreements

All groups $G, H, F, \dots$ are connected complex reductive algebraic groups, $X, Y, \dots$ stand for complex algebraic varieties, and $V, U, W, \dots$ denote finite dimensional complex vector spaces, unless specified otherwise.

For G acting on an irreducible X , $\mathbb{C}(X)^G$ and $\mathbb{C}[X]^G$ denote the field of *rational invariants*, and the algebra of *polynomial invariants*.

For an exceptional triple (H, G, X) , $\nu(H, G, X) := \text{tr.deg.} \mathbb{C}(X)^H = \text{tr.deg.} \mathbb{C}(X)^G$.

Let G be a simply connected semisimple group, and $H \subset G$ be a maximal semisimple subgroup. Then either (1) $G = G_1 \times G_2 \supset H = H_1 \times G_2$, where G_1 is simple, and $H_1 \subset G_1$ is a maximal semisimple subgroup, or (2) $H = H_{12} \times F \subset G = H_1 \times H_2 \times F$, where $H_{12} \cong H_1 \cong H_2$ are simple, and H_{12} is embedded diagonally in $H_1 \times H_2$ ([2]).

Definition 2 *We say H is a straight subgroup if (1) holds, and a diagonal subgroup if (2) holds. We use the same terminology for the tangent algebras $\mathfrak{h} \subset \mathfrak{g}$.*

$O_X(G)$ is an *orbit in general position* of G , $G_*(X)$ is a *stabilizer in general position (SGP)* of G .

$Z(G)$ is the *center*, and G' is the *commutator subgroup* of G .

$X/G := \text{Spec} \mathbb{C}[X]^G$ denotes the *categorical quotient*.

A triple (H, G, X) is called *semisimple, etc.*, if both H and G are semisimple, etc. A triple (H, G, V) is called *irreducible, orthogonal, etc.*, if both H and G are irreducible, orthogonal, etc., on V .

For a simple, connected, simply connected group G of rank r denote by $\phi_1, \dots, \phi_r$ the fundamental representations of G in standard ordering (see, for example [3]). Sometimes we denote by *Spin* the spin representation ϕ_k or half-spin representations ϕ_k and ϕ_{k-1} of B_k or D_k .

4 Where is the difficulty

Lemma 2 *Let (H, G, X) be an exceptional triple. Suppose G acts on a variety Y , and $\pi : X \rightarrow Y$ is a surjective G -equivariant homomorphism. Then (H, G, Y) is also an exceptional pair.*

Proof. Consider $\pi^* : \mathbb{C}(Y) \rightarrow \mathbb{C}(X)$, where $(\pi^* f)(v) = f(\pi(v))$. Then π^* is G -equivariant and injective. Hence, $\mathbb{C}(Y)^H \neq \mathbb{C}(Y)^G$ would imply $\mathbb{C}(X)^H \neq \mathbb{C}(X)^G$. $\square$

Assume $X = V$ is a vector space, and H, G are reductive.

Corollary 1 *Let $U \subset V$ be a G -submodule. If (H, G, V) is exceptional then (H, G, U) is also exceptional.*

Proof. Since G is reductive, there exists a G -invariant subspace U' such that $V = U \oplus U'$. Denote by $\pi : V \rightarrow U$ the projection on U parallel to U' . Then π is G -equivariant, and, by Lemma 2, (H, G, U) is exceptional. $\square$

Since V decomposes into a direct sum of G -submodules, the triple (H, G, V) is in a certain sense a sum of exceptional triples, in which the group is irreducible. Note, however, that if (H, G, U) and (H, G, W) are exceptional triples, the triple $(H, G, U \oplus W)$ is not at all guaranteed to be exceptional. For example, the triple $(Sp_{2n}, SL_{2n}, \mathbb{C}^{2n})$ is exceptional, and the triple $(Sp_{2n}, SL_{2n}, \mathbb{C}^{2n} \oplus \mathbb{C}^{2n})$ is not.

Our main two questions therefore are:

1. What are the exceptional triples (H, G, V) with G irreducible, and
2. How exactly two exceptional triples can combine to make another exceptional triple.

In paper [16], we partially answered the first question, namely, classified exceptional triples (H, G, V) with both H and G irreducible on V (for convenience, we summarized it here in section 7). The second question presents a much harder problem due to a generally complicated structure

of V as a G -module. The main reason is that proper submodules of V do not have to be faithful even if V is faithful. This phenomenon is sometimes called “blinking kernels”. As a simplest example, consider a group $G := G_{12} \times G_{23} \times G_{13}$ acting on a vector space $V = V_1 \oplus V_2 \oplus V_3$, where G_{ij} acts nontrivially on V_i and V_j , and trivially on the other summand. In case of blinking kernels, it’s very hard to see the orbit structure of V .

4.1 Branching law

To approach our classification, we need to know how an irreducible G -module branches into irreducible H -modules. Assume (H, G, V) is an exceptional triple, G is orthogonal. It turns out that for such triples the branching law is simple: an irreducible G -module decomposes into a sum of at most two H -irreducible modules. We describe this law precisely in Lemmas 3 and 4.

Denote by $(\cdot, \cdot)$ an invariant symmetric bilinear form on V . A subspace $W \subset V$ is called non-degenerate, if the restriction of $(\cdot, \cdot)$ on W is non-degenerate.

Lemma 3 *Suppose $W \subset V$ is a non-degenerate H -submodule. Then W is also a G -submodule. Consequently, if H -action on W is orthogonal, then W is a G -submodule.*

Proof. Denote by $W^\perp$ the orthogonal complement of W in V . Since W is non-degenerate, we have $V = W \oplus W^\perp$. Take the orthogonal projection $P : V \longrightarrow W^\perp$. Since W is H -invariant, P commutes with H . Denote $F(v) := (Pv, Pv)$. F is an H -invariant, and, therefore, a G -invariant polynomial. Since $W = \text{Ker } F$, W is G -invariant. $\square$

As known from linear algebra, a minimal orthogonal H -submodule $W \subset V$ is either irreducible, or $W = U \oplus U^*$, where U is irreducible and non-orthogonal.

Definition 3 *We say that a minimal orthogonal G -submodule $W \subset V$ is solid if W is H - and G -irreducible; half-split if W is G -irreducible and $W = U \oplus U^*$, U is H -irreducible; and split if $W = U \oplus U^*$, U is H - and G -irreducible. We will also say that a submodule W is solid (half-split, split), if all of its minimal orthogonal G -submodules are such.*

Lemma 3 implies

Lemma 4 *V decomposes into direct sum of solid, half-split and split G -submodules.*

5 Preliminaries

This is a collection of facts we use throughout the paper.

Let $G_x \subset G$ denote the stationary subgroup of a point $x \in X$.

Definition 4 *Suppose there is a subgroup $G_*(X) \subset G$ such that G_x is a conjugate of $G_*(X)$ for x in a dense subset in X . Then we call $G_*(X)$ a stabilizer in general position (SGP) for the action of G on X .*

For a reductive G , and $X = V$ a vector space, a SGP $G_*(V)$ always exists [12], [6].

Lemma 5 ([9]) *Assume $H, G, G_* := G_*(X)$ are reductive. Then (H, G, X) is exceptional if and only if the triple (G, H, G_*) is a factorization, i.e., $G = HG_*$.*

Proposition 2 *Assume H, G, G_* are reductive. Then (H, G, X) is exceptional if and only if $(G', H', (G_*)')$ and $(Z(G), Z(H)_{Z(G)}, Z(G_*)_{Z(G)})$ are factorizations, where $Z(G)$ denotes the center of G , and $Z(H)_{Z(G)}, Z(G_*)_{Z(G)}$ denote the projections of the centers $Z(H)$ and $Z(G_*)$ into $Z(G)$.*

Proof. This is a composition of Lemma 5 and Theorem 3.2 from [10]. $\square$

Lemma 6 *Assume H, G, G_* are reductive. If (H, G, X) is exceptional then the triple (H', G', X) is exceptional.*

However, the converse does not hold. Consider a triple $(H, G, X) = (\{id\}, \mathbb{C}^*, \mathbb{C})$. Then $(H', G', X) = (\{id\}, \{id\}, \mathbb{C})$ is exceptional, where (H, G, X) is not.

Proof. As follows from Proposition 2, $(G, H, G_*(X))$ is a factorization implies $(G', H', (G_*(X))')$ is a factorization. For $x \in X$, we have $(G_x)' \subseteq G_x \cap G' = (G')_x$. In particular, $(G_*(X))' \subseteq (G')_*(X)$. Hence, $(G', H', (G')_*(X))$ is also a factorization, that is, (H', G', X) is exceptional. $\square$

Lemma 7 *Let (H, G, X) be an exceptional triple, $G = G_1 \times G_2 \supset H = H_1 \times G_2$. Then either (H_1, G_1, X) is exceptional, or $\dim pr_{G_2} G_*(X) > 0$.*

Proof. Consider the maps

$$\begin{array}{ccc} X/H_1 & \xrightarrow{f} & X/G_1 \\ \pi_H \downarrow & & \downarrow \pi_G \\ X/H & \xlongequal{\quad} & X/G, \end{array}$$

where f is G_2 -equivariant, and π_H, π_G are the morphisms of factorization by G_2 . Assume $\dim pr_{G_2} G_*(X) = 0$. Since $\dim pr_{G_2} G_*(X) = (G_2)_*(X/G_1)$, a generic π_G -fiber has (the maximal) dimension equal to $\dim G_2$. Since the diagram is commutative, and the dimension of a π_H -fiber is less or equal $\dim G_2$, we obtain $f = id$, that is, (H_1, G_1, X) is exceptional. $\square$

Claim 1 *Let $N \subset G$ be a normal subgroup. Then $\mathbb{C}(X)^G = \mathbb{C}(X/N)^{G/N}$.*

6 Outlines

In this section we proof Proposition 1 and outline the proof of Theorem 1.

6.1 Proof of Proposition 1.

Let $H \subset G \subset SO(V)$ be orthogonal reductive linear groups. Proposition 2 allows us to assume that $Z(H) = Z(H)_{Z(G)}$, i.e., $Z(H) \subseteq Z(G)$. By definition of T , we have $Z(G) = Z(H) \times T$.

Assume (H, G, V) is exceptional. Since a SGP of a reductive orthogonal group is reductive ([6], see also [18]), Lemma 6 proves (i). Furthermore, since $Z(H)$ has a trivial SGP on $V/(G' \times T)$, the triple $(H', G' \times T, V)$ is exceptional by Lemma 7, that is, T acts trivially on $\mathbb{C}[V]^{G'} = \mathbb{C}[V]^{H'}$, and we get (ii).

Now suppose conditions (i), (ii) hold. Denote by $X := V/G' = V/H'$. By (ii), we have $\mathbb{C}[X]^T = \mathbb{C}[X]$. By Claim 1, we have $\mathbb{C}[V]^G = \mathbb{C}[X]^{Z(G)} = \mathbb{C}[X]^{T \times Z(H)} = \mathbb{C}[X]^{Z(H)} = \mathbb{C}[V]^H$, i.e., (H, G, V) is exceptional. $\square$

6.2 Outlines of the proof of Theorem 1.

We divided Theorem 1 into Theorems 2, 3, and 4. Theorems 2 and 3 treat two particular cases, namely, locally trivial and strongly faithful triples, and we prove them later in sections 9 and 10. Theorem 4 is proved in this section.

As Lemma 5 suggests, one can try to apply Onishchik's classification of factorizations for reductive groups [9] to classify exceptional triples. However, we cannot apply this classification directly, since for an arbitrary complicated G -module V one cannot say much about $G_*(V)$, see an example at the end of section 4. What we do is we apply Onishchik's classification to locally trivial and to strongly faithful triples, and then treat the general case manually based on these particular cases, see Theorem 4.

Proposition 3 *Suppose (H, G, V) is semisimple orthogonal exceptional, H is maximal in G . (H, G, V) is locally trivial if and only if H is diagonal (see Definition 2).*

Proof. The "only if" implication follows from the definition of a locally trivial triple.

Suppose H is diagonal and assume (H, G, V) is not locally trivial. Then there exists a non-zero G -irreducible submodule $W \subset V$ such that $H_1 \times H_2$ acts nontrivially on W . Let $W = \phi_1 \otimes \phi_2 \otimes \phi_{12}$, where $\phi_1, \phi_2, \phi_{12}$ are irreducible representations of H_1, H_2 , and H_{12} respectively. By Lemma 4, either W is H -irreducible, or $W = U \oplus U^*$, where U is H -irreducible. That is, $\phi_1 \otimes \phi_2$ restricted to H_{12} , is equal either to (a) ψ or to (b) $\psi \oplus \psi^*$, where ψ is H_{12} -irreducible.

The option (a) is impossible, see, for example, [5]. Assume (b) holds. Denote by Λ_1 and Λ_2 the highest weights of ϕ_1 and ϕ_2 . Then $\Lambda = \Lambda_1 + \Lambda_2$ is the highest weight of ψ , and $\Lambda - M$ is the highest weight of ψ^* , where M is a non-negative linear combination of simple roots of H_{12} .

In particular, we have $(\Lambda - M, \Lambda - M) = (\Lambda, \Lambda)$. However, this is impossible. We have $(\Lambda - M, \Lambda - M) = (\Lambda, \Lambda) - (\Lambda, M) - (M, \Lambda - M) < (\Lambda, \Lambda)$, since $\Lambda - M$ is dominant. $\square$

Theorem 2 *Suppose (H, G, V) is semisimple indecomposable locally trivial orthogonal exceptional triple, H is maximal in G . Then (H, G, V) has diagram one of **T1** – **T9**. Conversely, all diagrams **T1** – **T9** correspond to exceptional triples, assuming that in diagram **T9** one of the two indecomposable components of G satisfies Lemma 18.*

Theorem 3 *Suppose (H, G, V) is semisimple indecomposable strongly faithful orthogonal exceptional triple, H is maximal in G . Then (H, G, V) has diagram one of **F1** – **F10**. Conversely, all diagrams **F1** – **F10** correspond to exceptional triples.*

We prove these theorems in sections 9 and 10.

Let us consider the general case.

Theorem 4 *Assume a semisimple indecomposable orthogonal exceptional triple (H, G, V) is neither locally trivial, nor strongly faithful. Then (H, G, V)*

has a diagram

where the action of the subgroup $SO_8 \subset G$ on $V_1 \oplus V_2$ is isomorphic, up to a trivial component, to $t\phi_1$, $t \leq 3$. Conversely, any triple with such diagram is exceptional.

Proof. In this proof, all vertices in all diagrams correspond to simple subgroups/ G -submodules, unless specified otherwise.

Since (H, G, V) is not locally trivial, H is a straight (see Definition 2) subgroup in G by Proposition 3, that is, the top of a diagram for (H, G) looks like

where H_1 is maximal in G_1 . Since G is not strongly faithful, we have $k > 1$. Assume $G_2 \neq \{id\}$. Denote by $\tilde{V} \subset V$ the sum of all submodules where G_1 acts nontrivially, that is, the sum of all submodules connected to G_1 . Since (H, G, V) is indecomposable, one of $G_2, \dots, G_k$, say G_2 , acts nontrivially on $\tilde{V}$, i.e., G_2 is connected to $\tilde{V}$.

Let $\tilde{W} \supseteq \tilde{V}$ be a simple submodule connected to G_2 , and $W \supset \tilde{W}$ be the minimal orthogonal submodule containing $\tilde{W}$. By Lemma 4, either $W = \tilde{W}$, or $W = \tilde{W} \oplus \tilde{W}^*$.

Denote by G^W the product of all normal subgroups in G connected to W (as well as to $\tilde{W}$), and let H^W be the projection of G^W on H . Then, by Corollary 1, (H^W, G^W, W) is exceptional, and, by definition of W , strongly faithful. Since $G_1 \subset G^W$, we have $H^W \neq G^W$, and therefore, by Theorem 3, (H^W, G^W, W) has a diagram

This proves that (H, G, V) has a following diagram (here the vertices are not necessarily simple):

Furthermore, Theorem 3 implies $V = V^0 \oplus V^1 \oplus \dots \oplus V^k$, where (H, G, V^0) is a trivial triple, and (H, G, V^i) , $i > 0$, is isomorphic to one of

Hence, (H_1, G_1, V) is isomorphic, up to a trivial component, to

We only have to prove now that $t \leq 3$.

Lemma 8 (H_1, G_1, V) is exceptional.

By Theorem 3, Lemma 8 implies $t \leq 3$.

Proof of Lemma 8. Denote $V^I = V^1 \oplus \dots \oplus V^k$, and let $G^I \subset G$ be the product of all simple normal subgroups in G acting nontrivially on V^I . Let H^I be the projection of G^I on H . By Corollary 1, (H^I, G^I, V^I) is exceptional.

We have $H^I = SO_7 \times SO_3^{(1)} \times \dots \times SO_3^{(m)}$, $G^I = SO_8 \times SO_3^{(1)} \times \dots \times SO_3^{(m)}$ for some $m > 0$ (note that $m = 0$ would mean (H, G, V) is decomposable).

Denote $S := (SO_3^{(1)} \times \dots \times SO_3^{(m)})_*(V^I/SO_8)$. Let us show that $\dim S = 0$.

Note that each $SO_3^{(i)}$ is connected to exactly one of $V_1, \dots, V_k$. Indeed, assume the opposite, say, $SO_3^{(1)}$ is connected to V_1 and V_2 . Then $(H^I, G^I, V_1 \oplus V_2)$ is isomorphic to

which is not exceptional by Theorem 3, in contradiction to Corollary 1. Hence, we may assume for every $i = 1 \dots m$ that $SO_3^{(i)}$ is connected to V_i and disconnected from all other V_j .

Denote $S_i := (SO_3^{(i)})_*(V_i/SO_8)$. Then $S_i = pr_{SO_3^{(i)}}(SO_8 \times SO_3^{(i)})_*(V_i)$, and, therefore, S_i contains $pr_{SO_3^{(i)}}S$. However, $S_i \cong pr_{SO_3}(SO_8 \times SO_3)_*(\phi_1 \otimes \phi_1) = \{id\}$, and therefore, $S = id$. By Lemma 7, it means that (H_1, G_1, V^I) , as well as on (H_1, G_1, V) , is exceptional. Lemma 8 is proved. $\square$

Let us prove the last statement for the theorem.

Consider a triple (H, G, V) that satisfies the conditions of the theorem. Then (SO_7, SO_8, V) is exceptional by Theorem 3. In other words, $V/SO_8 = V/SO_7$, and, by Claim 1, we have $\mathbb{C}[V]^G \cong \mathbb{C}[V/SO_8]^{G/SO_8} \cong \mathbb{C}[V/SO_7]^{H/SO_7} \cong \mathbb{C}[V]^H$. $\square$

7 Irreducible exceptional triples

This is a partial summary of [16].

Let (H, G, V) be an irreducible semisimple triple. Theorem 5 classifies exceptional triples (H, G, V) up to an explicit equivalence relation called castling transform (Definition 5 below).

Suppose $F \subseteq SL(U)$. Consider the group $G = F \times SL(W) \subset SL(U \otimes W)$, $\dim W \leq \dim U$, and the group $\check{G} = F \times SL(\check{W}) \subset SL(U^* \otimes \check{W})$, where $\dim \check{W} = \dim U - \dim W$. Then $\check{G}_*(U^* \otimes \check{W}) \cong G_*(U \otimes W)$ [4]. In particular, if $\dim U = \dim W + 1$, then $F_*(U) \cong G_*(U \otimes W)$.

Definition 5 *We say that the (linear) group $\check{G}$ is an immediate castling transform of the group G , and vice versa. We say that a group $\tilde{G}$ is a castling transform of G , and write $\tilde{G} \bowtie G$, if $\tilde{G}$ is a result of a sequence of immediate castling transforms of G . We will say that two triples $(\tilde{H}, \tilde{G}, \tilde{V})$ and (H, G, V) are congruent, and write $(\tilde{H}, \tilde{G}, \tilde{V}) \bowtie (H, G, V)$ if they are isomorphic up to simultaneous castling transform.*

One can show that if (H, G, V) is exceptional and $(\tilde{H}, \tilde{G}, \tilde{V}) \bowtie (H, G, V)$, then $(\tilde{H}, \tilde{G}, \tilde{V})$ is also exceptional, and $\nu(\tilde{H}, \tilde{G}, \tilde{V}) = \nu(H, G, V)$.

Denote $H_{s,t,k} = SL_s \times SL_t \times X_k \subset G_{s,t,k} = SL_{st} \times X_k \subset SL_{stk}$, where $X_k \subseteq SL_k$ is irreducible, and $st > k$. The group $H_{s,t,k}$ may have zero, one, or more invariants on $\mathbb{C}^{stk}$, depending on s, t , and k values, and also on X_k , while $G_{s,t,k}$ has zero invariants.

Theorem 5 *Suppose (H, G, V) is exceptional. If $\nu(H, G, V) = 0$, (H, G, V) is congruent to $(H_{s,t,k}, G_{s,t,k}, \mathbb{C}^{stk})$ or to one of the triples **L1-L7**. Otherwise, (H, G, V) is congruent to one of the triples **A1-A10**. Conversely, all triples **L1-L7**, **A1-A10**, as well as their congruents, are exceptional.*

In diagram **L5**, Y_k is a maximal subgroup in $X_k \subseteq SL_k$. For triples **A1-A10**, we indicated the generators degrees for the algebra of invariants, which is always polynomial.

8 Factorizations

In this section we bring down definitions and theorems from Onishchik's paper [10] (Theorems 3.1-3.3, 4.3), mostly simplified for our needs, to be used in sections 9 and 10. Note that here we use the word "triple" for a triple of groups.

Assume G , H , S are reductive groups.

A triple of groups (G, H, S) , where $H, S \subset G$, is called a *factorization* if $G = HS$.

$\mathfrak{g}, \mathfrak{h}, \dots$ denote the tangent Lie algebras of the groups $G, H, \dots$. A triple of Lie algebras $(\mathfrak{g}, \mathfrak{h}, \mathfrak{s})$, where $\mathfrak{h}, \mathfrak{s} \subset \mathfrak{g}$, is called a *factorization* if $\mathfrak{g} = \mathfrak{h} + \mathfrak{s}$.

Lemma 9 *A triple (G, H, S) is a factorization if and only if a triple $(\mathfrak{g}, \mathfrak{h}, \mathfrak{s})$ is a factorization.*

Assume $\mathfrak{g}$ and $\mathfrak{h}$ are semisimple. For a reductive algebra $\mathfrak{a}$, denote by $\mathfrak{a}'$ the semisimple part of $\mathfrak{a}$.

Lemma 10 *A triple $(\mathfrak{g}, \mathfrak{h}, \mathfrak{s})$ is a factorization if and only if a triple $(\mathfrak{g}, \mathfrak{h}, \mathfrak{s}')$ is a factorization. In particular, if $\mathfrak{s}$ is commutative, then the factorization $(\mathfrak{g}, \mathfrak{h}, \mathfrak{s})$ is trivial.*

We say a triple $(\mathfrak{g}, \mathfrak{h}, \mathfrak{s})$ is *symmetric* to the triple $(\mathfrak{g}, \mathfrak{s}, \mathfrak{h})$. A triple symmetric to a factorization is also a factorization.

Lemma 11 *Suppose $\mathfrak{g}$ is simple, $\mathfrak{h}, \mathfrak{s}$ semisimple, and the triple $(\mathfrak{g}, \mathfrak{h}, \mathfrak{s})$ is a nontrivial factorization. Then $(\mathfrak{g}, \mathfrak{h}, \mathfrak{s})$ is isomorphic or symmetric to one of the factorizations from Table O. Conversely, any triple from Table O is a factorization.*

Table O.

$\mathfrak{g}$	$\mathfrak{h}$	$\mathfrak{h} \hookrightarrow \mathfrak{g}$	$\mathfrak{s}$	$\mathfrak{s} \hookrightarrow \mathfrak{g}$
$\mathfrak{sl}_{2n}, n > 1$	$\mathfrak{sp}_{2n}$	ϕ_1	$\mathfrak{sl}_{2n-1}$	$\phi_1 \oplus id$
$\mathfrak{so}_{2n}, n > 1$	$\mathfrak{sl}_n$	$\phi_1 \oplus \phi_{n-1}$	$\mathfrak{so}_{2n-1}$	$\phi_1 \oplus id$
$\mathfrak{so}_{4n}, n > 1$	$\mathfrak{sp}_{2n} \oplus \mathfrak{sl}_2$	$\phi_1 \otimes \phi_1$	$\mathfrak{so}_{4n-1}$	$\phi_1 \oplus id$
$\mathfrak{so}_7$	$\mathfrak{g}_2$	ϕ_1	$\mathfrak{so}_6$	$\phi_1 \oplus id$
$\mathfrak{so}_7$	$\mathfrak{g}_2$	ϕ_1	$\mathfrak{so}_5$	$\phi_1 \oplus 2id$
$\mathfrak{so}_8$	$\mathfrak{so}_7$	$\mathfrak{spin}$	$\mathfrak{so}_7$	$\phi_1 \oplus id$
$\mathfrak{so}_8$	$\mathfrak{so}_7$	$\mathfrak{spin}$	$\mathfrak{so}_6$	$\phi_1 \oplus 2id$
$\mathfrak{so}_8$	$\mathfrak{so}_7$	$\mathfrak{spin}$	$\mathfrak{so}_5$	$\phi_1 \oplus 3id$
$\mathfrak{so}_{16}$	$\mathfrak{so}_9$	$\mathfrak{spin}$	$\mathfrak{so}_{15}$	$\phi_1 \oplus id$

A semisimple algebra is called *strongly semisimple* if all its ideals have rank > 1 . For a reductive $\mathfrak{a}$, we denote by $\mathfrak{a}^s$ the maximal strongly semisimple subalgebra of $\mathfrak{a}$. We call $\mathfrak{a}^s$ the *strongly semisimple part* of $\mathfrak{a}$. We have a decomposition $\mathfrak{a} = \mathfrak{a}^s \oplus \mathfrak{a}^r$, where $\mathfrak{a}^r$ is a sum of all rank 1 ideals of $\mathfrak{a}$ and the center $\mathfrak{z}(\mathfrak{a})$.

Lemma 12 *Let $(\mathfrak{h}^r)_{\mathfrak{g}^r}$, $(\mathfrak{s}^r)_{\mathfrak{g}^r}$ denote the projections of $\mathfrak{h}^r$, $\mathfrak{s}^r$ on $\mathfrak{g}^r$. Then $(\mathfrak{g}, \mathfrak{h}, \mathfrak{s})$ is a factorization if and only if both $(\mathfrak{g}^s, \mathfrak{h}^s, \mathfrak{s}^s)$ and $(\mathfrak{g}^r, (\mathfrak{h}^r)_{\mathfrak{g}^r}, (\mathfrak{s}^r)_{\mathfrak{g}^r})$ are factorizations.*

Suppose $\mathfrak{s}$, $\mathfrak{g}$ are strongly semisimple, $\mathfrak{s} = \mathfrak{s}_1 \oplus \dots \oplus \mathfrak{s}_l$, where all $\mathfrak{s}_i$ are simple ideals. Assume $\mathfrak{h} \subsetneq \mathfrak{g}$ is a maximal semisimple subalgebra.

Lemma 13 *Suppose $\mathfrak{h}$ is a straight subalgebra, i.e., $\mathfrak{h} = \mathfrak{h}_1 \oplus \mathfrak{g}_2 \subset \mathfrak{g}_1 \oplus \mathfrak{g}_2$, where $\mathfrak{g}_1$ is simple, and $\mathfrak{h}_1$ is maximal in $\mathfrak{g}_1$. Denote by $\mathfrak{s}_{i1}$ the projection of $\mathfrak{s}_i$ on $\mathfrak{g}_1$. Then $(\mathfrak{g}, \mathfrak{h}, \mathfrak{s})$ is a factorization if and only if $(\mathfrak{g}_1, \mathfrak{h}_1, \mathfrak{s}_{i1})$ is a factorization for some i .*

9 Locally trivial pairs

In this section we prove Theorem 2.

Let (H, G, V) be an orthogonal locally trivial triple, H is maximal in G . According to Proposition 3, H is a diagonal subgroup, that is, $H = H_{12} \times F \subset G = H_1 \times H_2 \times F$, where $H_{12} \cong H_1 \cong H_2$ are simple, and H_{12} is embedded diagonally in $H_1 \times H_2$. Denote $G_* := G_*(V)$. According to Lemma 5, (H, G, V) is exceptional if and only if (G, H, G_*) is a factorization. Note that, since $F \subset H$, the triple of groups (G, H, G_*) is a factorization if and only if $(H_1 \times H_2, H_{12}, S)$ is a factorization, where S denotes the projection $pr_{H_1 \times H_2} G_*$.

Denote $V = V_1 \oplus V_2 \oplus V_{12}$, where H_1 acts trivially on V_2 , H_2 acts trivially on V_1 , and $H_1 \times H_2$ acts trivially on V_{12} .

Lemma 14 *(H, G, V) is exceptional if and only if $(H_{12}, H_1 \times H_2, (V_1 \oplus V_2)/F)$ is exceptional.*

Proof. By Claim 1, $\mathbb{C}[V]^H = \mathbb{C}[V]^G \iff \mathbb{C}[V/F]^{H_{12}} = \mathbb{C}[V/F]^{H_1 \times H_2} \iff \mathbb{C}[(V_1 \oplus V_2)/F]^{H_{12}} = \mathbb{C}[(V_1 \oplus V_2)/F]^{H_1 \times H_2}. \square$

Lemma 15 *Suppose we have a reductive triple $(H_{12}, H_1 \times H_2, X)$ where $X := X_1 \times X_2$, so that the restrictions $(H_{12}, H_1 \times H_2, X_i) = (H_{12}, H_i, X_i)$ are trivial, $i = 1, 2$. Suppose the SGP's $S_{ii} := (H_{12})_*(X_i)$, $i = 1, 2$, are reductive. Then $(H_{12}, H_1 \times H_2, X)$ is exceptional if and only if (H_{12}, S_{11}, S_{22}) is a factorization.*

Proof. We have $(H_1 \times H_2)_*(X) \cong S_{11} \times S_{22}$, and $S_{12} := \overline{(H_{12})_*(X)} \cong (S_{11})_*(X_2)$. The triple $(H_{12}, H_1 \times H_2, X)$ is exceptional $\iff \overline{O_X(H_{12})} =$

$\overline{O_X(H_1 \times H_2)} \iff \dim O_X(H_{12}) = \dim O_X(H_1 \times H_2) \iff \dim H_{12} - \dim S_{12} = \dim(H_1 \times H_2) - \dim(S_{11} \times S_{22}) \iff \dim H_{12} - \dim S_{22} = \dim S_{11} - \dim S_{12} \iff \dim O_{X_2}(H_{12}) = \dim O_{X_2}(S_{11}) \iff \text{the triple } (S_{11}, H_{12}, X_2) \text{ is exceptional} \iff (H_{12}, S_{11}, S_{22}) \text{ is a factorization. } \square$

Back to the original triple (H, G, V) , denote $S_i = G_*(V_i)$, $S_{ii} = (H_{12})_*(V_i/F)$, $i = 1, 2$. Then S_{ii} is isomorphic to the projection of S_i on H_i . In particular, S_{ii} is reductive.

Lemma 16 *If (H, G, V) is exceptional, then necessarily (H_{12}, S_{11}, S_{22}) is a factorization. If $(V_1 \oplus V_2)/F = V_1/F \times V_2/F$, this condition is also sufficient.*

Proof. (H, G, V) is exceptional if and only if $(H_{12}, H_1 \times H_2, (V_1 \oplus V_2)/F)$ is exceptional (Lemma 14). Since $(V_1 \oplus V_2)/F \longrightarrow V_1/F \times V_2/F$ is surjective and G -equivariant, $(H_{12}, H_1 \times H_2, V_1/F \times V_2/F)$ is exceptional (Lemma 2). Now we can apply Lemma 15. $\square$

Proof of Theorem 2. Suppose (H, G, V) is exceptional. Following Lemma 16, we are looking for orthogonal actions of H on V_i , $i = 1, 2$, such that (H_{12}, S_{11}, S_{22}) is a factorization.

Suppose (H_{12}, S_{11}, S_{22}) is a nontrivial factorization. Then we are in the conditions of Lemma 11. Therefore, (H_{12}, S_{11}, S_{22}) is isomorphic or symmetric to one of the triples from Table O. Hence, we have to find all the actions $H : V_i$ such that H_{12} and S_{ii} appear in the same line in Table O. Let's call such actions candidates.

Note that V may only have solid or split summands (see Definition 3). Using [3], [4], we first find all solid candidates. The result is all the entries in Table T except for the last one.

Now let us prove that the only split candidate is the last entry of Table T. Let $V_i = U \oplus U^*$, where the action $H : U$ is not orthogonal.

Assume F is trivial. Then [3], [4] imply that $H = H_{12} : U$ is isomorphic to $SL_{2n} : \phi_1 \oplus \phi_1^*$.

Let us prove that there does not exist a split candidate with F not trivial. We may assume that U is irreducible.

Note that an action $H : V_i$ is a candidate $\iff (S_{ii}, H_{12}, V_i)$ is exceptional $\implies (S_{ii}, H_{12}, U)$ is exceptional.

Consider H acting on U as $SL_n \times SL_k : \phi_1 \otimes \phi_1$, $n \geq k \geq 2$. Then $S_{ii} = SL_{n-k} \times T_{k-1}$, where T_{k-1} is a torus. Since $k \geq 2$, (S_{ii}, H_{12}, U) is not exceptional. Even more so (S_{ii}, H_{12}, U) is not exceptional when H acts on U as $SL_n \times X_k : \phi_1 \otimes \phi$, $X_k \subseteq SL_k$, whether $H_{12} = X_k$ or $H_{12} = SL_n$. Note that since only the groups SL_n and SO_n appear in the first column of Table O, the last option we have for a candidate is $H_{12} = SO_n$, $F \subseteq SL_k$,

$U = \phi_1 \otimes \phi$. Here we have $S_{ii} = SO_{n-2k}$, or id if $n \leq 2k$. Since $k \geq 2$, this action is not a candidate.

We proved that $H : V_i$ has to be isomorphic to one of the following:

Table T.

H	$H : V_i$	S_{ii}	$S_{ii} \hookrightarrow H$
SL_4	ϕ_2	Sp_4	ϕ_1
SO_7	$Spin$	G_2	ϕ_1
SO_{12}	$Spin$	SL_6	$\phi_1 \oplus \phi_5$
SO_7	ϕ_1	SO_6	$\phi_1 \oplus id$
SO_8	$Spin$	SO_7	ϕ_1
SO_{2n}	ϕ_1	SO_{2n-1}	$\phi_1 \oplus id$
SO_7	$2\phi_1$	SO_5	$\phi_1 \oplus 2id$
SO_8	$2\phi_1$	SO_6	$\phi_1 \oplus 2id$
SO_8	$3\phi_1$	SO_5	$\phi_1 \oplus 3id$
$SO_8 \times SO_3$	$\phi_1 \otimes \phi_1$	SO_5	$(\phi_1 \oplus 3id) \otimes id$
SL_{2n}	$\phi_1 \oplus \phi_{2n-1}$	SL_{2n-1}	$\phi_1 \oplus id$

It's now easy to make sums $V = V_1 \oplus V_2 \oplus V_{12}$ so that (H, G, V) is exceptional. The result is diagrams **T1-T8**.

Now suppose (H_{12}, S_{11}, S_{22}) is a trivial factorization, say, $H_1 = S_{11}$. As in the beginning of the section, let S denote the projection of G_* to $H_1 \times H_2$.

Lemma 17 *Suppose $H_1 = S_{11}$. Then*

(a) $H_1 = SL_2$. Moreover, for any minimal orthogonal subspace $W \subseteq V_1$, the action $H : W$ is isomorphic to $SL_2 \times Sp_{2n} : \phi_1 \otimes \phi_1$, $n \geq 1$.

(b) (H, G, V) is exceptional if and only if $S \neq H_{12}$.

Proof. (a) follows from [3], [4].

We have $(G, H, G_*(V))$ is a factorization $\iff (SL_2 \times SL_2, SL_2^{diag}, S)$ is a factorization. Since the projection of S on the first factor is SL_2 , this triple is always a factorization unless $S = SL_2^{diag} = H_{12}$. Lemma 17 is proved. $\square$

In [19], we find the following description of groups $K = SL_2 \times \check{K} \subset SO(V)$ such that the projection of SGP $K_* := K_*(V)$ on the first factor is SL_2 .

Consider a rooted tree T with vertices $0, 1, \dots, q$, where 0 is the root. Assign a weight $d(i)$ to each vertex such that $d(i)$ is either a positive integer or ∞ . Assume that (a) $d(0) = 1$, (b) each vertex i with $d(i) = \infty$ has degree 1 (here the degree of a vertex is the number of adjacent vertices), and (c) if

(i, j) is an edge with $d(j) = \infty$, then $d(i) > 1$. We say a vertex i is *finite* if $d(i) < \infty$, and an edge (i, j) is *finite* if both i and j are finite.

Let $\check{K}$ be a product of $Sp_{2d(i)}$ over all finite vertices except for the root, and K be a product of $Sp_{2d(i)}$ over all finite vertices. Assign a vector space $W_{(i,j)}$ to each edge (i, j) , namely, let $W_{(i,j)} = \mathbb{C}^{2d(i)} \otimes \mathbb{C}^{2d(j)}$ for a finite (i, j) , and $W_{(i,j)} = S_0^2 \mathbb{C}^{2d(i)}$ for an edge (i, j) with $d(i) = \infty$.

Now let V be a direct sum of $W_{(i,j)}$ over all edges of T . The group K acts on V in the following way: each factor $Sp_{2d(i)}$ of K acts (a) on the first factor of $W_{(i,j)}$ for all finite vertices j connected to i by an edge, and also (b) on $W_{(i,j)}$ for all infinite j connected to i by an edge. For example, a tree with 2 vertices corresponds to the group $K = SL_2 \times Sp_{2d(1)}$ acting on $\mathbb{C}^2 \otimes \mathbb{C}^{2d(1)}$.

Lemma 18 ([19]) *Consider a tree as above and assume that the corresponding linear group $K = SL_2 \times \check{K} \subset SO(V)$ is indecomposable, i.e., K is not a direct sum of proper linear subgroups. The projection of $K_* := K_*(V)$ on the first factor is SL_2 if and only if*

- (I) *all vertices i with $d(i) > 1$ have degree at most 2;*
- (II) *for all edges (i, j) such that $d(i) > 1$, $d(j) > 1$, one of the vertices i, j has degree 1.*

Suppose a tree T satisfies the conditions of the lemma and assume that $d(1) = 1$. It's easy to check that if vertex 1 belongs to the connected component of the root, then the projection of K_* on the subgroup $Sp_{2d(0)} \times Sp_{2d(1)} \cong SL_2 \times SL_2$ is the diagonal subgroup SL_2^{diag} . If 0 and 1 are disconnected, then this projection is $SL_2 \times SL_2$.

Consider the tree T_G corresponding to G . Since (H, G, V) is indecomposable, T_G is either connected or T_G has two connected components: one for H_1 , and one for H_2 . We saw that $S = SL_2^{diag}$ if and only if H_1 and H_2 belong to one connected component on T_G . Hence, by Lemma 17, we obtain the following diagram **T9** corresponding to an exceptional (H, G, V) :

In this diagram, we replaced all finite vertices of T_G from the connected components of H_1 and H_2 by the very left and very right circles in the

middle level of the diagram correspondingly, and then substituted all the edges with vertices in the bottom level.

The theorem is proved. $\square$

10 Strongly faithful pairs

Here we prove Theorem 3.

Let (H, G, V) be an orthogonal strongly faithful triple, H is maximal in G . By Proposition 3, H is a straight subgroup: $H = H_1 \times G_2 \subset G = G_1 \times G_2$, where H_1 is maximal in G_1 , and G_1 is simple.

Take $V_1 \subset V$ a minimal orthogonal G -invariant subspace.

Suppose V_1 is solid (see Definition 3). Then, by Theorem 5, (H, G, V_1) has diagram one of **F1-F5**.

Suppose V_1 is half-split. Then, as follows from [3], [4], and Lemma 5, (H, G, V_1) has diagram **F6**.

Now suppose V_1 is split, that is, $V_1 = U \oplus U^*$, where (H, G, U) is irreducible exceptional non-orthogonal. By Theorem 5, the action of G on U is isomorphic to one of the actions in Table F1 below:

Table F1.

	G	U
1	SL_n	ϕ_1
2	$SL_n \times X_k, X_k \subseteq SL_k, k \leq n$	$\phi_1 \otimes \phi$
3	$SL_{n_1} \times \dots \times SL_{n_s} \times X_k, k < n_1 \dots n_s$	$\phi_1 \otimes \dots \phi_1 \otimes \phi$
4	SO_{12}	ϕ_5
5	$SO_7 \times SL_k, k = 2, 5$	$\phi_1 \otimes \phi_1$
6	$SO_8 \times SL_k, k = 2, 3, 5, 6$	$\phi_1 \otimes \phi_1$

Following Lemma 13, we are interested in projections of the SGP $G_*(V_1)$ onto simple normal subgroups of G . Note that in case 3 we are only interested in the projections onto the last factor X_k .

In case 1, $G = SL_n$, we obtain an exceptional (by Lemma 13) triple with diagram **F7**.

In case 2, take $X_k = SL_k$. Then $G_*(V_1) = SL_{n-k} \times T_{k-1}$, where T_{k-1} is a torus, and $SL_{n-k} \subset SL_n$. Since $k > 1$, $(G, H, G_*(V_1))$ is not a factorization by Lemma 11, that is, (H, G, V_1) is not exceptional. This implies (H, G, V_1) is not exceptional for any $X_k \subset SL_k$, and therefore, it is not exceptional in case 3 either.

In cases 4, 5 and 6, $G_*(V_1) = SL_4$, $SO_{7-2k} \subset SO_7$, and $SO_{8-2k} \subset SO_8$, respectively, and (H, G, V_1) is not exceptional by Lemma 11.

Suppose there are other minimal orthogonal G -invariant subspaces $V_2, \dots, V_k \subset V$. From the explicit description we obtained for the action of G on V_1 , we see that necessarily for all i $V_i \cong V_1$ as a G -module. Then we simply check directly if $(H, G, V_1 \oplus V_2 \oplus \dots)$ is exceptional. Table F2 below shows this calculation. As a result, we obtain diagrams **F8-F10** (cases 1,3,5 resp. in Table F2).

Table F2.

	G	$G : V$	$G_*(V)$
1	SO_7	$2\phi_1$	SO_5
2	SO_7	$3\phi_1$	SO_4
3	SO_8	$2\phi_1$	SO_6
4	SO_8	$\phi_1 \oplus \phi_3$	G_2
5	SO_8	$3\phi_1$	SO_5
6	SO_8	$4\phi_1$	SO_4
7	SO_{2n}	$2\phi_1$	SO_{2n-2}
8	$SO_8 \times SO_3$	$2(\phi_1 \otimes \phi_1)$	T_1
9	$SO_8 \otimes SO_3$	$\phi_1 \otimes \phi_1 \oplus (\phi_1 \otimes \phi_1)^*$	id
10	SL_n	$2(\phi_1 \oplus \phi_{n-1})$	SL_{n-2}

The theorem is proved.
